

Constructive Truth-State, Semantic Time, and Adjudicative Will

A formal lab note on frozen registries, interpretation drift, residual selection, social adjudication, and participatory description

Lu Semita

EmergenceByDesign

Lab Notes · Version 1.0 · 8 September 2026

Standing

Formal laboratory note. Shareable working result. No ownership, priority, or discovery claim is made over established mathematics, logic, philosophy, physical theory, cited results, or standard proof methods. Formal results, conjectures, ontological commitments, and empirical social hypotheses are explicitly separated.

Standing, authorship, and provenance

This document records a formalization developed within ongoing laboratory notes associated with Lu Semita / EmergenceByDesign. It is circulated as a shareable mathematical and conceptual working note. No claim of ownership, priority, or discovery is made over established mathematics, classical logic, philosophy of language, formal systems, Gödel incompleteness, computability theory, physical theory, or cited results.

The surrounding laboratory program draws from the author's own research and from earlier co-authored work with Jenny Lorraine Neilsen. Any reference in related materials to TUFT refers to Neilsen's independent work and its claims are not invoked here unless expressly identified and adopted. No TUFT-specific claim is used as a premise in this note. Mention of Neilsen is included solely to preserve attribution and does not imply her review, participation in, agreement with, or endorsement of this document.

Established mathematical background such as gauge theory or the Hopf fibration remains available independently of any TUFT-specific interpretation and is not claimed as proprietary work.

Terms such as registry, semantic time, residual will, frame-dual, constructive truth-state, and Λ -irreducibility belong to the laboratory vocabulary used to organize the reasoning. The formal claims below are stated directly enough to be evaluated without adopting that vocabulary.

Abstract

A formal inscription can be frozen, but the act of interpreting it cannot be frozen merely by preserving its marks. This note extends the previously formalized class-closure and frame-dual results by indexing closure to both a registry and an interpretation. It then proves several limited structural propositions concerning inscription/interpretation identity, residual selection, consensus as a separate predicate, asymmetric truth-status revision, and representation insufficiency. On that formal skeleton it states four larger conjectures: semantic non-hermeticity, participatory continuum, residual will, and constructive truth-state. Finally it separates those conjectures from empirical hypotheses concerning delegated verification, social compression, edge obscurity, and survival-oriented allocation of scrutiny. No observer-independent reality is assumed as an undeclared oracle; realism and anti-realism remain optional ontological commitments.

Status key

FORMAL RESULT

Claim derived from the declared registry assumptions or elementary set/function logic. These are the strongest claims in the note.

CONJECTURE

A proposed structural extension not yet established as a universal theorem. It is presented with an explicit falsification surface.

EMPIRICAL HYPOTHESIS

A claim about human, institutional, or social behavior. It requires observation and may be population-, context-, or resource-dependent.

ONTOLOGICAL COMMITMENT

A premise concerning what exists or how reality relates to description. Such commitments are declared rather than smuggled in as neutral background.

Companion relation

This note incorporates and extends the formal results previously frozen in “Class-Level Closure and Frame-Dual Non-Progress” (Lu Semita · EmergenceByDesign, Lab Notes, 7 September 2026). The earlier class-closure result remains intact relative to a frozen registry and interpretation; the present note adds semantic time and interpretive delta as explicit dimensions of adjudication.

0. Standing: no privileged external oracle

A common account of knowledge begins by assuming an independently existing state X and treating description as a map $X \rightarrow R$. That construction already assumes that X exists independently of representation, that X carries determinate structure prior to description, that the representation refers to X , and that some notion of correspondence is meaningful. Those may be reasonable commitments. They are not neutral primitives.

Accordingly, this framework does not begin by assuming an observer-independent truth object. If desired, such a commitment may be added explicitly as a realism axiom:

REAL: $\exists X$ whose existence and relevant structure do not depend upon the registry.

A correspondence relation would then require an additional commitment:

$$\text{Corr}(R, X).$$

Neither REAL nor Corr follows merely from the existence of a formal description. Conversely, the assertion that no observer-independent X exists would also constitute an additional ontological commitment. The formal framework therefore begins prior to either assertion.

1. Registered description

At time t , let R_t denote a registered inscription or descriptive state. A registry may include

$$R_t = (D_t, L_t, Q_t, T_t, W_t, A_t),$$

where, according to context:

- D_t is the declared domain;
- L_t is the language and definitions;
- Q_t is the quantified structure;
- T_t is the target;

- W_t is the admitted witness or proof-object class;
- A_t is the declared acceptance relation.

The inscription alone does not provide its complete interpretation. Introduce I_t as an interpretive transformation applied to R_t . Thus the operative meaning at time t is represented schematically by

$$M_t = I_t(R_t).$$

No claim is made that M_t equals an observer-independent reality. It records the meaning currently assigned within the descriptive system.

2. Truth-status as an adjudicated state

Let the declared status set be

$$\Sigma = \{\text{ACCEPT}, \text{REJECT}, \text{OPEN}\},$$

or some richer declared status set. Let C_t denote the comparators, evidence, measurements, derivations, witnesses, precedents, or other admitted constraints available at time t . Let J_t denote the operative adjudication rule. Then the assigned status of proposition ϕ is

$$S_t(\phi) = J_t(I_t(R_t), C_t, \phi).$$

This is an assigned truth-status. The equation does not claim that $S_t(\phi)$ equals an observer-independent truth of ϕ . Such an identification would require an additional bridge.

3. Frozen inscription does not freeze interpretation

Suppose the inscription is frozen at time t_0 :

$$R_t = R_{t_0} \text{ for all } t \geq t_0.$$

Nothing in this identity entails

$$I_t = I_{t_0}.$$

Hence it may occur that

$$R_t = R_{t_0}, \text{ while } I_t(R_{t_0}) \neq I_{t_0}(R_{t_0}).$$

Proposition 3.1 - Inscription-Interpretation Distinction

Identity of inscription does not entail identity of interpretation unless interpretive identity is separately assumed or derived.

Proof.

The functions I_t and I_{t_0} constitute separate mathematical objects from R_{t_0} . Equality of their common argument does not imply equality of their outputs unless the functions themselves agree on that argument. Therefore $R_t = R_{t_0}$ alone cannot establish $I_t(R_t) = I_{t_0}(R_{t_0})$. QED.

4. Semantic time

A frozen artifact may persist while its interpretive environment changes. Define the interpretive trajectory

$$t \mapsto I_t.$$

We call this semantic time. Semantic time need not correspond to physical time in any deeper ontological sense. It records change in interpretation across ordered adjudicative states.

Define $\Delta_I(t_0, t_1)$ for change of interpretation and $\Delta_R(t_0, t_1)$ for change of inscription. Then the following combination is possible:

$$\Delta_R = 0, \quad \Delta_I \neq 0.$$

A historical document therefore provides a persistent reference surface against which semantic movement can be detected. It does not constitute a hermetic semantic seal.

5. Revised Frozen-Registry Principle

Let (R_0, I_0) denote the inscription together with the declared interpretation under which the original question is adjudicated. Let

$$Q := \forall x \in C \ P(x).$$

If

$$(R_0, I_0) \vdash Q,$$

then, relative to that frozen pair, a subsequent unsupported repetition of $\neg Q$ adds no new mathematical information. Likewise, if an admissible counterexample establishes $(R_0, I_0) \vdash \neg Q$, reasserting Q without identifying a proof defect, registry change, interpretive change, or new evidence adds no mathematical information.

$$\text{Closure}_-(R_0, I_0)(Q).$$

A later reinterpretation does not retroactively falsify the original derivation. It produces a new interpretive relation requiring explicit comparison.

6. Class closure and the frame-dual loop

For a fixed admissible class C and predicate P ,

$$Q = \forall x \in C \ P(x).$$

Classical quantifier negation gives

$$\neg Q \Leftrightarrow \exists x \in C \ \neg P(x).$$

Define

$$D(Q) = \neg Q, \quad D(\neg Q) = Q.$$

$$D^2 = \text{id}.$$

Repeated movement $Q \rightarrow \neg Q \rightarrow Q \rightarrow \neg Q \rightarrow \dots$ adds no mathematical information unless additional content enters, such as class-level proof, counterexample, proof defect, structural obstruction, registry delta, interpretive delta, or new admissible evidence. This extends the prior Frame-Dual Non-Progress Theorem by recognizing interpretive change explicitly as a substantive transition.

7. OPEN remains epistemic

Define $\text{OPEN}_{(R,I)}(Q)$ by

$$(R,I) \not\models Q \quad \text{and} \quad (R,I) \not\models \neg Q.$$

OPEN records a state of adjudication. It does not introduce a third object-level alternative to Q and $\neg Q$. Under a different interpretation I' , the status may change. Thus

$$\text{OPEN}_{(R,I)}(Q) \text{ does not imply } \text{OPEN}_{(R,I')}(Q).$$

8. Residual selection

Suppose the registered conditions permit more than one admissible adjudication rule. Let $J(R,I,C)$ be the class of adjudication procedures compatible with the declared constraints. Suppose there exist $J_1, J_2 \in J$ such that

$$J_1(I(R), C, \varphi) \neq J_2(I(R), C, \varphi).$$

Then the registered information does not uniquely determine a terminal status. Some further selector must distinguish among the admissible adjudication procedures. Let

$$\Omega : J \rightarrow J^*.$$

We call Ω a residual selector.

9. Residual Selection Theorem

Theorem 9.1 - Residual Selection

If two adjudication procedures remain admissible under the same registered conditions and assign different terminal statuses, then no unique terminal status follows from those registered conditions alone.

Proof.

Assume the registered conditions uniquely determine status S . Then every adjudication procedure compatible with those conditions must produce S . But by hypothesis there exist admissible J_1 and J_2 with $J_1(\dots) \neq J_2(\dots)$. Therefore the status is not uniquely determined by the registered conditions. An additional condition or selector is required. QED.

10. Adjudicative will

We reserve the term will for the residual act of selection not already forced by the registered conditions. Thus will is not defined as an ontological power that creates an observer-independent reality, nor as arbitrary human preference. Formally, will occupies the role

$$W : J \rightarrow J^*$$

when no prior registered condition uniquely fixes J^* . This permits will to appear through individual choice, collective vote, convention, institutional authority, automatic threshold, inherited standard, machine recommendation, randomization, cultural norm, legal rule, or disciplinary custom. If that mechanism itself was not already necessitated by the predecessor registry, selecting it constitutes an additional commitment.

11. Delegation does not eliminate selection

A community may attempt to reduce arbitrary choice by delegating adjudicative authority to comparators that resist immediate preference. Examples include observation, measurement, reproducibility, formal proof, consistency, machine checking, prediction, adversarial review, specialist judgment, and institutional consensus.

Let those constraints be $C_1, \dots, C_n$. An adjudicative policy may weight them:

$$J = F(w_1 C_1, \dots, w_n C_n).$$

But the questions remain: Why these comparators? Why these weights? Why this function? Why this threshold? If the predecessor registry does not uniquely answer those questions, delegation relocates the residual selection rather than eliminating it.

Proposition 11.1 - Delegation

Delegation of adjudicative selection is not equivalent to elimination of adjudicative selection. The selector may move upstream into the choice of comparator, weighting, threshold, verifier, or jurisdiction.

12. Consensus as a separate predicate

Let a community K contain members $k_1, \dots, k_n$. Define $\text{Accept}_K(\varphi)$ as some declared aggregate acceptance predicate. This remains distinct from $\Gamma \vdash \varphi$. It also remains distinct from any separately posited correspondence predicate.

$$\text{Accept}_K(\varphi) \neq \text{Derivable}(\varphi)$$

unless a bridge equating them is separately asserted. Community acceptance may influence public truth-status. It does not become formal derivation merely through consensus.

13. Public proof as a mediated object

A privately constructed proof does not become publicly adjudicable until represented. The chain may be written schematically as

$$P_{\text{private}} \rightarrow R \rightarrow I_K(R) \rightarrow V_K \rightarrow S_K.$$

Here P_{private} is the original construction; R is the communicable representation; I_K is shared interpretation; V_K is verification; and S_K is assigned public status. External scrutiny therefore never operates on an entirely unrepresented private object. It operates on some representation of it. Additional formalization may reduce ambiguity. It does not remove representation itself.

14. The interpretive regress

Suppose one attempts to fix interpretation by publishing an auxiliary specification J_0 describing how R_0 must be interpreted. But J_0 is itself an inscription. Therefore it admits an interpretation $I(J_0)$. A further specification may constrain that interpretation, but the new specification also becomes an object of interpretation.

$$R_0 \rightarrow J_0 \rightarrow J_1 \rightarrow J_2 \rightarrow \dots$$

This does not prove that invariant interpretation is impossible. It proves only that additional inscription does not escape the requirement for interpretation merely by being additional inscription.

15. Non-Hermeticity Conjecture

Conjecture 15.1 - Semantic Non-Hermeticity

No finite descriptive artifact, solely by virtue of its inscription, guarantees invariant interpretation across every admissible future interpretive frame.

Additional constraints may narrow the interpretive class:

$$I_0 \supseteq I_1 \supseteq I_2 \supseteq \dots$$

But no assumption presently supplied requires the intersection of all such interpretive classes to contain exactly one interpretation for all possible future adjudicators. This is a conjecture about descriptive systems. It should not be confused with Gödel's incompleteness theorems.

16. Relation to Gödel

Gödel's incompleteness theorems concern formally specified systems satisfying particular mathematical conditions. The present framework asks a different question: What happens when formal systems themselves must be interpreted, instantiated, communicated, and granted jurisdiction by agents operating within other descriptive systems?

The point is not that this framework proves a stronger Gödel theorem. Rather, formal incompleteness leaves untouched many practical bridge questions: why this formal system, why this interpretation, why these primitives, why this physical correspondence, why this verifier, why this acceptance criterion, and why this translation between formal and informal claims. Those questions occur at the interface between formal description and its use.

17. Constructed truth-state

Let V_t be the set of propositions assigned accepted status at time t :

$$V_t = \{\varphi : S_t(\varphi) = \text{ACCEPT}\}.$$

Then the publicly operative truth-state changes through time:

$$V_t \rightarrow V_{(t+1)}.$$

Define

$$\Delta_t^+ = V_{(t+1)} \setminus V_t, \quad \Delta_t^- = V_t \setminus V_{(t+1)}.$$

These represent newly accepted and newly rejected descriptions. Nothing in set theory requires $|\Delta_t^+| = |\Delta_t^-|$, nor does it require a reversal at a later stage to restore the exact prior state. Therefore adjudicated truth-state evolution need not be symmetric.

18. Asymmetric Revision Proposition

Proposition 18.1 - Asymmetric Revision

Changes in publicly assigned truth-status need not occur symmetrically. There is no general requirement that every added accepted proposition correspond to one removed proposition, nor that reversal of one registry component restore the previous accepted set.

This follows directly because Δ_t^+ and Δ_t^- are independent set differences unless additional symmetry is imposed. Truth-status can therefore be constructed and destroyed at unequal rates within an evolving descriptive system.

19. Formal monotonicity versus social nonmonotonicity

For a fixed classical deductive system, adding premises may preserve previously derivable propositions:

$$\Gamma \subseteq \Gamma' \Rightarrow \text{Th}(\Gamma) \subseteq \text{Th}(\Gamma').$$

But public adjudication need not behave monotonically because any of I_t , J_t , C_t , or R_t may change. Therefore formal monotonicity does not imply historical monotonicity of accepted truth-status. This allows descriptions once treated as valid to lose that status without requiring logical contradiction inside the original frozen system.

20. Participatory Continuum Conjecture

Conjecture 20.1 - Participatory Continuum

The operative world available to an embedded descriptive agent may not consist merely of a fixed external reality passively discovered and increasingly described. The agent, its descriptions, its actions, its comparators, and the environment may participate recursively in the production of successive operative states.

$$O_t \xrightarrow{\text{description/action}} O_{(t+1)}.$$

Here O_t denotes an operative world-state rather than an asserted observer-independent ontology. The conjecture permits $O_{(t+1)}$ to depend partly upon descriptions and actions generated from O_t . Thus description may participate causally in the conditions subsequently described. This is stronger than saying merely that beliefs change. It remains weaker than asserting without proof that consciousness literally creates all reality.

21. Discovery and construction as unresolved orientations

Two familiar orientations can be represented.

$$\text{Discovery: } X \rightarrow R_t$$

$$\text{Constructive: } R_t \rightarrow O_{(t+1)}$$

Nothing in the registry formalism alone requires either orientation to possess exclusive jurisdiction. A mixed relation is also possible:

$$O_t \leftrightarrow R_t.$$

Thus the question “Are we discovering reality or participating in its construction?” cannot be settled merely by presupposing one orientation in the notation used to ask it.

22. Shared descriptive frame

Let a community K possess a shared representational map

$$\Phi_K : X \rightarrow R_K.$$

Two distinctions may exist with $x \neq y$ while

$$\Phi_K(x) = \Phi_K(y).$$

Then the shared frame cannot distinguish x from y . If some validity predicate T satisfies

$$T(x) \neq T(y),$$

then T does not factor through Φ_K . The shared representation is insufficient to determine the target distinction. This is the general Λ -form encountered elsewhere: representation collapses a distinction still relevant to the target predicate.

23. Boundary concentration

Suppose common verification procedures resolve most distinctions represented by Φ_K . Any remaining error, if one exists, may lie in distinctions not expressed by those common procedures.

Conditional boundary statement

If a candidate has passed all checks representable within a shared frame, then any surviving defect must occupy a distinction not detected by those checks.

This does not imply that obscure objections are correct. It implies that obscurity alone cannot disqualify an objection when the unresolved distinction lies outside the common frame.

24. Delegated Adjudication Hypothesis

Hypothesis 24.1 - Delegated Adjudication

When the cost or technical difficulty of direct verification exceeds an individual's available capacity, the individual increasingly substitutes proxy evaluation for direct evaluation.

Such proxies may include reputation, institutional standing, majority opinion, specialist consensus, citation count, credential, machine confidence, prior reliability, social trust, or perceived risk of dissent. This is an empirical hypothesis about behavior. It is not derived from logic alone.

25. Social Compression Hypothesis

A large community cannot normally reproduce every underlying argument in full. Instead it compresses them into reports such as accepted, rejected, expert consensus, verified, fringe, or open. These labels allow rapid social coordination. They also discard information.

$$\Psi : E \rightarrow L$$

may map a rich evidentiary state E into a small label set L . Many evidentiary states may therefore occupy the same fibre $\Psi^{-1}(\ell)$. A social label does not preserve every distinction present in the evidence it summarizes.

26. Survival-Strategy Hypothesis

Hypothesis 26.1 - Survival Allocation

For many agents, rapid classification of reports by trusted social signals provides greater practical survival value than independently reconstructing every underlying argument.

If so, social cognition will tend to allocate limited attention toward source reliability, coalition signals, prior success, conformity, authority, reputational risk, and local usefulness rather than toward complete reconstruction of every edge-case argument. This would make such behavior adaptive under resource constraints without making the resulting classifications infallible.

27. Edge-Adjudication Problem

Suppose most members of community K evaluate proposition ϕ through a compressed representation $\Phi_K(\phi)$, while a validity-relevant distinction δ is invisible under Φ_K . Suppose a specialist s possesses a finer map Φ_s for which

$$\Phi_s(\delta) \neq 0.$$

Then the specialist objection may be valid while remaining unintelligible within the common frame. This creates an asymmetry between a widely understandable apparent solution and a narrowly understandable valid objection. The commonness of the first does not logically defeat the second.

28. Solver-Verifier Gap

Let $G(x)$ represent the capacity required to generate candidate x and $V(x)$ the capacity required to verify it independently. Let evaluator k possess capacity C_k . When

$$V(x) > C_k,$$

direct verification is unavailable to evaluator k . The evaluator must either remain uncommitted, obtain additional capacity, delegate verification, or assign status using proxy evidence. As increasingly capable systems generate objects for which $V(x) \gg C_k$ for most users, public truth-status becomes increasingly mediated through verification chains.

29. Verification-chain distinction

A chain may have the form

candidate $\rightarrow$ formalization $\rightarrow$ machine checker $\rightarrow$ specialist review $\rightarrow$ institution $\rightarrow$
community status.

Each arrow constitutes a distinct bridge. Therefore the following predicates should not be conflated:

- Typechecks(x);

- FormalStatementMatch(x);
- InformalStatementMatch(x);
- ProblemMatch(x);
- IndependentReview(x);
- CommunityAccepts(x).

They may correlate. They are not identical by logic alone.

30. Constraint-resistance and outsourced will

Communities often grant greater epistemic authority to constraints that appear harder for an individual to manipulate voluntarily. Thus measurement may outweigh desire, reproduction may outweigh anecdote, formal proof may outweigh reputation, and machine checking may outweigh informal confidence.

greater resistance to immediate choice = greater adjudicative weight

is therefore a plausible structural tendency. But the rule granting that weight is itself selected. Societies may attempt to bind will through constraints resistant to will while the selection of those constraints remains another adjudicative act. We call this constraint outsourcing.

31. Residual Will Conjecture

Conjecture 31.1 - Residual Will

Every practically instantiated system of shared truth adjudication contains some residual selection that cannot be eliminated merely by replacing one selector with another comparator, unless the replacement is itself uniquely necessitated by the predecessor registry.

The residual selection may be displaced, distributed, automated, or obscured. It is not thereby shown to have disappeared.

delegation of will $\neq$ elimination of will.

32. Constructive Truth-State Conjecture

Conjecture 32.1 - Constructive Truth-State

Publicly operative truth-states emerge through an evolving interaction among description, interpretation, constraint, adjudication, selection, and subsequent action.

$$V_t \rightarrow \text{action}_t \rightarrow R_{t+1} \rightarrow I_{t+1} \rightarrow V_{t+1}.$$

This recursive relation permits descriptions to participate in producing later conditions of description. Truth-status is therefore not modeled merely as passive accumulation. It may be constructed, revised, abandoned, restored, or transformed along a temporally ordered path.

33. Path dependence

Because R_t , I_t , C_t , and J_t may all change, the adjudicative process need not be path-independent. It may occur that

$$R_2 = R_0, \text{ while } V_2 \neq V_0$$

because $I_2 \neq I_0$ or $J_2 \neq J_0$. Returning to the same inscription therefore need not restore the same operative truth-state. This is semantic hysteresis.

34. No final escape by description alone

The framework repeatedly encounters the same structure. A description intended to remove ambiguity becomes another object requiring interpretation. A verifier intended to remove judgment becomes another object whose jurisdiction requires acceptance. A consensus intended to settle uncertainty becomes another social fact requiring interpretation. A measurement intended to remove choice requires a selected instrument, calibration, and comparator. A frozen registry intended to remove temporal change persists inside a changing interpretive environment.

Thus successive attempts to eliminate the descriptive boundary may instead relocate it. This is the proposed higher-order Λ structure. It is not claimed here as a universal theorem. It constitutes the organizing conjecture to be tested domain by domain.

35. Main formal results presently established

- Inscription identity does not imply interpretation identity.
- A frozen class-level proposition and its negation form a two-state frame-dual orbit under classical logic.
- Repeated reversal without new evidence, proof, defect, obstruction, registry change, or interpretive change supplies no mathematical progress.
- OPEN is an adjudicative status, not a third object-level truth value.
- If multiple admissible adjudication procedures yield different terminal statuses, the registered conditions do not uniquely determine the status.
- Delegation of adjudication does not logically imply elimination of the act of selecting the delegated authority.
- Community acceptance and formal derivability are different predicates unless a bridge equating them is declared.
- Accepted truth-state may change non-symmetrically through time.
- A shared representation may fail to preserve validity-relevant distinctions.

These provide the formal skeleton. They do not require the stronger ontological conjectures below.

36. Principal conjectures

C1 - Semantic Non-Hermeticity

No finite inscription guarantees invariant interpretation across all future interpretive frames solely by virtue of its inscription.

C2 - Participatory Continuum

Description and action may participate recursively in production of subsequent operative states rather than serving only as passive observations of a fixed independent reality.

C3 - Residual Will

Practical systems of truth adjudication retain some residual selection whenever their own registered constraints fail uniquely to determine terminal status.

C4 - Constructive Truth-State

Public truth-status evolves recursively and path-dependently through description, interpretation, constraint, adjudication, and action.

These conjectures should remain distinct until stronger bridges are established.

37. Empirical hypotheses

H1 - Delegated Adjudication

Agents increasingly use proxy verification when direct verification exceeds available capacity.

H2 - Social Compression

Communities compress rich evidentiary states into low-dimensional labels for practical coordination.

H3 - Edge Obscurity

Validity-relevant objections outside a shared descriptive frame may become less socially legible precisely because they concern distinctions absent from the common representation.

H4 - Survival Allocation

Under limited resources, agents preferentially allocate attention toward socially useful reliability signals rather than complete independent reconstruction of every claim.

These hypotheses may prove partly true, false, conditional, or population-dependent without affecting the preceding formal propositions.

38. Falsification and attack surface

The framework invites attack at the level appropriate to each claim.

- Formal propositions may be refuted by identifying an invalid inference, inconsistent definition, hidden assumption, or countermodel.
- Semantic Non-Hermeticity may be attacked by exhibiting a finite inscription that guarantees invariant interpretation across the quantified future interpretive class, with that class itself declared.
- Residual Will may be attacked by deriving a unique terminal selector from the predecessor registry without introducing an additional unregistered commitment.
- Participatory Continuum may be attacked empirically or conceptually by showing that the proposed feedback contributes no state-forming role beyond passive representation under the declared model.

- Delegated-adjudication and survival-allocation hypotheses require observational testing and may fail in particular populations or domains.
- The framework does not treat disagreement, obscurity, consensus, or institutional status as substitutes for any of these burdens.

39. Final statement

The framework does not begin from the assertion that observers merely discover a fully formed reality. It also does not begin from the assertion that observers simply invent reality. Both positions require commitments beyond the minimal registry.

What can presently be said more carefully is this: a descriptive agent never publicly adjudicates an unmediated oracle. The agent operates through registered distinctions, interpretations, comparators, inferential structures, and selected jurisdictions. Those structures persist through time imperfectly. Their meanings may change while their inscriptions remain fixed. Their accepted truth-states may expand and contract asymmetrically. Their verification may become increasingly delegated. And when the registered constraints fail uniquely to determine a terminal status, some additional selection enters. We call the residual selection will.

Whether that will merely selects descriptions of an independently existing reality, participates causally in constructing the operative world subsequently encountered, or occupies some relation not captured by that dichotomy remains an open ontological question. The framework therefore refuses to solve the question by inserting its answer as an undeclared primitive.

Methodological demand

Every purportedly unavoidable truth assignment should expose the registry, interpretation, comparator, bridge, adjudicator, and residual selector through which it became unavoidable. Only then can necessity be distinguished from convention, derivation from delegation, correspondence from assumption, and closure from a truth-state constructed by the rules chosen to adjudicate it.
